Abstract

In this paper, we discuss a number of experiments to analyze the suitability of music label representations to predict certain audio features, such as danceability, loudness, or acoustiness ...

Keywords: Music information retrieval, Artificial intelligence

1 Introduction

Music information retrieval (MIR) is an interdisciplinary research field that encompasses the extraction, processing, and knowledge discovery of information contained in music. MIR research intersects with other fields, such as computer science, signal processing, musicology, and sociology. The field covers applications in recommendation systems, music classification, music source separation, and music generation, among others [?].

MIR applications often attempt to extract information from the music audio signal, but analyzing associated metadata is also a common practice. Audio signals are typically preprocessed and transformed into intermediate formats, such as frequency-based signal representations or hand-crafted audio features. Associated metadata, such as editorial information, lyrics, or user-generated content is usually in text format. However, metadata can be available

as images of videos, for example, when analyzing album artwork, or music videos.

Depending on the specific MIR application, researchers or practitioners expect different output values. For example, an application that extracts audio features might return values for the tempo, the key, or the sample rate. In more complex applications, where, for example, machine learning is used, applications might return the estimated emotion that a track produces on a listener, or the predicted music genre of a particular track.

Among potentially useful input and output values, research has proved Spotify audio features and Last.fm tags to be significant values to characterize music. Spotify audio features capture high-level information about the music signal. Examples of these values are energy, danceability, or valence, among others. Last.fm tags are text labels that users associate to particular tracks, artists or albums in the Last.fm website.

Both types of values have been used as input values mostly for classification tasks, such as music genre recognition, where, given Spotify features or Last.fm tags, the model estimates the music genres of a particular track. However, these values have not been used as target values by previous research, to the best of our knowledge. In particular, the focus of this article is on predicting Spotify audio features, given a set of Last.fm tags.

By predicting Spotify audio features, we explore the relationship between subjective perception and concrete musical features. This approach might help to identify patterns and hidden correlations between how music is perceived, consumed and discovered.

Additionally, predicted audio features could be used in recommendation systems to provide users with explainable recommendations. Music recommendations are not always easy to interpret from the perspective of the listener. Users often get recommendations without meaningful explanations or justifications. Therefore, by using predicted Spotify features as basis for recommendation, we can explain users why the algorithm suggests a particular track. This process could be part of an explainable recommendation pipeline, where users enter a set of tags, and they receive the predicted audio features, the closest tracks to those features, and the distance values between each track and the predicted features.

In the remainder of the article, we explain the data gathering and preparation process, as well as the data input formats and various models. We will explore various models for the same track and provide insights on how accurately the prediction can be, by using only Last.fm tags.

2 State of the Art

Citar: https://eden.dei.uc.pt/~ruipedro/publications/Conferences/SMC2021_Panda.pdf

In recent years, researchers have used Last.fm tags in classification and regression tasks. Several studies have used Last.fm to predict music sentiment or mood.

In the last decade, Last.fm tags have been a popular source of metadata for MIR tasks. Last.fm tags can contain information the genre, mood, and style of music, and might be use to characterize certain features of a music piece.

Last.fm tags can be useful when the audio signal available, for example, due to copyright limitations.

A number of studies have explored the use of Last.fm tags in MIR, and have shown promising results in predicting various audio features.

Researchers have used Last.fm tags. For example, Laurier et al. analyzed how Last.fm tags categorize mood. In their study, they created a semantic mood space based on Last.fm tags [?].

For example, Çano and Morisio discuss the process they follow to create a dataset of music lyrics annotated with Last.fm. In the creation process, they conclude that Last.fm tags are mostly related to music genre and positive moods [?]. In a similar direction, Bodó and Szilágyi generated a dataset for lyrics genre classification by combining the Last.fm with MusicBrainz data [?]. MusicBrainz ¹ is an online database of music editorial metadata. ¹

The Last.fm data has been the most widely used Last.fm dataset² in research. This dataset is a complementary dataset of the Million Song Dataset (MSD) [?].

Additionally, the Spotify audio features have been used in multiple studies. Historically, these features were also called "EchoNest audio features". Echonest was an online platform was was later acquired by Spotify.

Wang and Horvát use audio features to study differences between male and female artists [?]

In general, these studies confirm the possibility of extracting knowledge from Last.fm tags. To the best of our knowledge, no studies have addressed the problem of audio features regression, based solely on Last.fm tags.

Jamdar et al. used EchoNest audio features, combined with lyrics data to classify songs into emotion tags. These classes were first defined based on a Last.fm tags emotion mapping [?].

Similarly, Non-negative Matrix Factorization was applied in combination with EchoNest audio features for song recommendations [?].

P4kxspotify is a publicly available dataset that combines music review texts with Spotify audio features. The dataset creators argue that, although the terms of service prohibits scraping, their work is ethical [?].

In general, Spotify audio features have been used as predictive variables. We, to the best of our knowledge, are unaware of students that uses these features as target variables.

2.0.1 Machine Learning Models

Several studies have explored the use of machine learning models to predict audio features from audio metadata, such as Last.fm tags.

¹<https://musicbrainz.org/>

²Last.fm dataset, the official song tags and song similarity collection for the Million Song Dataset, available at: <http://millionsongdataset.com/lastfm>.

The experiments conducted in this study used two classical regression models, Boosted tree regressor and Bayesian ridge regressor. These two machine learning models that have been widely used in MIR.

Boosted tree regressor is a decision tree-based model that sequentially adds weak learners to the model to improve its performance. Bayesian ridge regressor, on the other hand, is a probabilistic model that uses Bayesian inference to estimate the parameters of the model.

Additionally, language models, such as GTP-2 have shown promising results in various natural language processing (NLP) and generation.

In this particular study, GTP-2 has been fine-tuned for regression tasks, and has shown good performance in predicting audio features from metadata.

This paper aims to apply the boosted tree regressor, Bayesian ridge regressor, and GTP-2 models to predict Spotify audio features from Last.fm tags. The experiments compare the performance of these models and evaluate their effectiveness in predicting various audio features. The results of these experiments will provide insights into the use of different machine learning models for MIR tasks and can have practical applications in music recommendation systems and genre or mood recognition.

To be Continued ...

3 Generating a Dataset

Before conducting experiments on predicting audio features from tags, we constructed a dataset, by gathering the data from the Last.fm and Spotify APIs.

3.1 A Single-user Dataset

Similar to other intelligent systems, recommender systems must be trained, by using user preference data, to produce adequate recommendations. For our recommendation framework, we have leveraged the knowledge discovery potential of large historical listening logs, gathered from Last.fm.

To characterize the preferences and context of the user, we have chosen to start with a simple scenario, where just data from a single user is available. By training our system with data from a single user, we also want to begin a discussion, given the following question: Is it possible to train recommender systems, and in particular, user-centric systems, by using a single-user dataset?

To the best of our knowledge, research on user-centric recommender systems has concentrated its efforts on explainable AI Wang et al. [2019], and also user-centered evaluation of these systems Knijnenburg et al. [2012]. We also argue that recommender systems that exploit the preferences of a single user, or a reduced number of users, might as well be considered as user-centric models.

3.2 Last.fm

Last.fm is a online music service for uses to keep track of their music listenting habits. Last.fm can also be considered as an community where users tag artists, albums, and tracks, according the the own perception of the user.

For nearly two decades, users have been contributing to Last.fm by tagging tracks with arbitrary text labels. These tags do not necessarily have to be single-worded. Users often use short sentences to define a song, such as ‘I like this track’, or ‘on the beach’.

Community-contributed tags from the Last.fm API. These tags are text labels that Last.fm users assign to artists, albums, or tracks. Users apply these tags to categorize music from their own perspective, which means that tags do not fit into any structured ontology or data model. Tags can refer to aspects such as genre, emotion, or user context.

3.2.1 Last.fm Tags

Last.fm uses the term *scrobble* to refer to a single track playback, in a particular moment. We have queried the Last.fm API to download the user’s scrobble logs, reported from 2007 to 2022. For each scrobble, we have gathered the following information:

- Track playback timestamp.
- Track MusicBrainz Identifier (MBID), if exists.
- Track name
- Artist name
- Track tags. If the track does not have any tags assigned, then artist tags have been used.

For each tag assigned to a track, or an artist, Last.fm includes a count property to indicate the popularity of the given tag for the track. Last.fm normalizes this value in the 0-100 range, so the most popular tag for a track can have a count value of 100.

Users normally listens to their favorite tracks many times, so the amount of individual tracks listened is much smaller than the number of track plays. In this case, the amount of individual tracks listened is about 20,000.

The format is as follows:

```
{
  "artist - name": {
    "eletronica": 100,
    "rock": 80,
    "pop": 45,
    "jazz": 0,
    "nu-jazz": 0,
    "country": 0,
    "soul": 0,
  }
}
```

3.3 Spotify

After gathering Last.fm data and identifying the unique tracks that represent the user music collection, we have collected Spotify audio features. For each of these individual tracks, we have downloaded the Spotify audio features specific to the given track.

The Spotify audio features are numerical values that represent high-level audio information computed from a specific track. These values characterize a track, musically speaking, by measuring relevant musical aspects.

The features provided by the Spotify API are acousticalness, danceability, duration_ms, energy, instrumentalness, key, liveness, loudness, mode, speechiness, tempo, and valence. Table 1 describes these features. The reader can find further details about each feature in the Spotify API documentation 4.

A small portion of the tracks do not have features available in Spotify, so they have been filtered out from our experiments.

After filtering songs that miss Last.fm tags or Spotify audio features, our dataset contains 14009 samples.

Track audio features from the Spotify API. These are attributes computed from the audio themselves. They are a way to describe music by using numerical values. For example, a danceability attribute of 0.95 means that a particular song is highly suitable for dancing.

3.4 Last.fm Tags Representations for Training

3.4.1 Tabular

Each tag is a column and each cell contains the popularity value of a tag for a track. A cell is 0 if a tag is missing for a track.

The number of columns is limited to the top-K tags.

3.4.2 Tabular Tokens

Tags are converted to text tokens. Columns represent token positions, and cells contain the token at a particular position, for a track. To tokenize tags, we have used the GTP2 tokenizer. Because the tokenizer requires a string as input, we have converted the set of tags for each track into a string. To *stringify* the tags, we have concatenated tags with multiple strategies:

- By including tag popularity: ‘rock 2, pop 1’.
- By repeating tags based on popularity: ‘rock rock, pop’.
- By ordering by popularity: ‘rock, pop’.

3.5 Training Data By Track

When generating training data by track, the tabular formats present sparsity problems.

For tabular representations, we need to define a fixed set of columns as tags. For most of tracks, most columns are ‘0’.

The sparsity of a matrix is the number of zero-valued elements divided by the total number of elements (e.g., $m * n$ for an $m * n$ matrix) is called the sparsity of the matrix

The mean and standard deviation for each variable are as follows:

Table 1 Audio features description

Feature	μ	σ
Danceability	0.599	0.193
Energy	0.631	0.233
Acousticness	0.221	0.302
Instrumentalness	0.514	0.382
Valence	0.435	0.279

Figure ?? represents the density function of each variable.

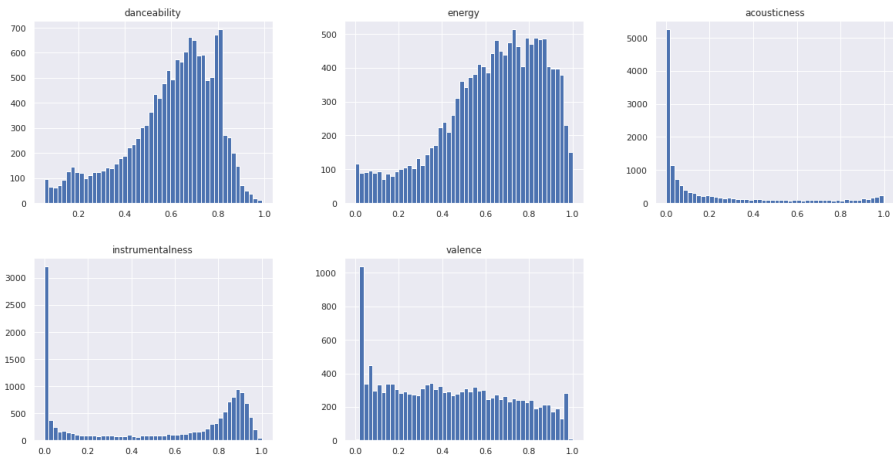

Fig. 1 Distribution of audio features

We can compare our single-user data with a bigger audio features dataset <https://www.kaggle.com/datasets/tomigelo/spotify-audio-features>. This dataset shows similar data distributions.

I have posted a question on the Spotify Developer forum, relative to the release of a dataset <https://community.spotify.com/t5/Spotify-for-Developers/May-I-publish-an-open-source-dataset-that-contains-Spotify-Audio/td-p/5529259>

3.6 Formatting Input Data for Predicting From Last.fm Tags

The input data passed to the XGBoost regressor is formatted in tabular format, as follows:

8 *Predicting Audio Features with Last.fm Tags*

- Given that $Tags_k$ is the set of most k frequent Last.fm tags in the user listening history and, where each $tag \in Tags_k$.
- Given that $Audio$ is the set of Spotify audio features, where each $feat \in Audio$.
- For each $track$:
 - $X_{track,tag}$ is the strength of tag for $track$. This value is in the 0–100 range.
 - $y_{track,feature}$ is the value of the audio feature y for $track$.

An example of this data format is provided in table ??.

Table 2 Tabular data format for Last.fm tags in XGBoost and Bayesian regressors

Track	$X_{electronic}$	$X_{ambient}$	$X_{...}$	y_{energy}	$y_{valence}$	$y_{...}$
Massive Attack - Blue Lines	62	6	...	0.496	0.947	...
The Beta Band - Squares	40	3	...	0.446	0.507	...
...

3.7 Formatting Input Data for Predicting From Tokens

In this particular case, the X values of the tabular input data are tokens. These tokens are obtained from passing the a string of concatenated Last.fm tags through a tokenizer. The formal definition of this data format is as follows:

- Given that X_l is the token vocabulary, where l is the maximum vocabulary length.
- Given that $Audio$ is the set of Spotify audio features, where each $feat \in Audio$.
- For each $track$:
 - $X_{track,n}$ is token found at position n , after tokenizing the tags string.
 - $y_{track,feature}$ is the value of the audio feature y for $track$.

An example of this data format is provided in table ??.

Table 3 Tabular data format for tokens in XGBoost and Bayesian regressors

Track	X_0	X_1	X_2	$X_{...}$	y_{energy}	$y_{valence}$	$y_{...}$
Massive Attack - Blue Lines	101	5099	6154	...	0.496	0.947	...
The Beta Band - Squares	101	4522	2600	...	0.446	0.507	...
...

3.8 Formatting Input Data for Predicting From Text

When using transformer models, the input data is a string. We must represent the Last.fm tags, which are initially in the $(tagname, tagpopularity)$ form, to a string.

After converting to a string, the formal definition of the input data is as follows:

- Given that X is tags represented as text.
- Given that $Audio$ is the set of Spotify audio features, where each $feat \in Audio$.
- For each $track$:
 - $X_{track,n}$ is set of tags for $track$, encoded as a single string.
 - $y_{track,feature}$ is the value of the audio feature y for $track$.

An example of this data format is provided in table ??.

Table 4 Text data format for tokens in XGBoost and Bayesian regressors

Track	X	y_{energy}	$y_{valence}$	$y...$
Massive Attack - Blue Lines	"hip hop, chill, bristol, ..."	0.496	0.947	...
The Beta Band - Squares	"alternative rock, folk, ..."	0.446	0.507	...
...

4 Experiments

We trained a commonly used machine learning models to predict an audio feature, given the set of tags for a particular track.

- Boosted tree regressor [?]
- Naive Bayes Regressor [?]
- Fine-tuned GPT-2 model

4.1 Boosted Tree Regressor

We configured the boosted tree regressor model with the training parameters listed in table ??.

4.2 Naive Bayes Regressor

The Naive Bayes Regressor, and in particular, Bayesian Ridge, is the model used for regression in this case.

The training parameters are listed in table ??.

4.3 Fine-tuned Transformer

tags with objective audio features, we can gain new insights into the complex relationship between perception and audio signal in music.

Our approach also presents limitations. One limitation is the assumption of a strong relationship between Last.fm tags and Spotify features, which may not be true in all cases. Future work could explore other sources of input values, possibly related to the user context, to improve the accuracy of the predictions.
